SEQUENTIAL ESTIMATION IN A GROWTH CURVE MODEL

Tatsuya Kubokawa (久保川達也)
University of Tsukuba

Abstract. For a coefficient matrix in the growth curve model, the paper gives a two-stage estimation procedure such that its risk function relative to arbitrary quadratic loss is bounded above by a preassigned constant, and the asymptotic efficiency is discussed. Also for powers of the generalized variance, a procedure with a bounded risk is developed and some domination results are shown.

Key words and phrases: Growth curve model; Two-stage sampling rule; Asymptotic efficiency; Point estimation.

1. INTRODUCTION

Let x_1, x_2, \dots be a sequence of mutually independent random vectors, x_i having p -variate normal distribution $N_p(B\xi a_i, \Sigma)$ where B ($p \times q$) is a known matrix of rank q , a_i ($r \times 1$) is a known vector and ξ ($q \times r$), Σ ($p \times p$) are unknown matrices. Denote $X_n = (x_1, x_2, \dots, x_n)$, $A_n = (a_1, a_2, \dots, a_n)$ and $\omega = (\xi, \Sigma)$. Then the random matrix X_n ($p \times n$) has $N_{p,n}(B\xi A_n; \Sigma, I_n)$, which is called a growth curve model by Potthoff and Roy (1964) and practical meaning and applications can be seen in their paper. If we put $q=p$ and $B=I$, we get an ordinary multivariate regression model.

Here we consider two problems for estimation of the coefficient matrix ξ and powers of the generalized variance $|\Sigma|^\alpha$, $\alpha \neq 0$ which are described below.

Problem (1). Given preassigned number $\varepsilon > 0$, we want to construct estimator $d_1 = d_1(\varepsilon)$ of ξ such that

$$R_1(\omega, d_1) = E_\omega[\text{tr } Q(d_1 - \xi)(d_1 - \xi)'] \leq \varepsilon \text{ for all } \omega, \text{ (consistency)}$$

where Q ($p \times p$) is a positive definite matrix.

Problem (2). For given $\varepsilon > 0$, we want to find estimator $d_2 = d_2(\varepsilon)$ of powers of the generalized variance $|\Sigma|^\alpha$ such that

$$R_2(\omega, d_2) = E_\omega[(d_2 - |\Sigma|^\alpha)^2] \leq \varepsilon \quad \text{for all } \omega \quad (\text{consistency}).$$

Throughout the paper, let m_0 be the smallest integer n ($\geq r$) such that the rank of A_n is r . In the case where Σ is known, we shall find a procedure satisfying the requirement of Problem (1). For integer $n \geq m_0$, MLE of ξ is given by

$$\hat{\xi}_0(n) = (B' \Sigma^{-1} B)^{-1} B' \Sigma^{-1} X_n A_n' (A_n A_n')^{-1},$$

and from Muirhead (1982) and Sugiura and Kubokawa (1988),

$$\begin{aligned} (1.1) \quad R_1(\omega, \hat{\xi}_0(n)) &= E[\text{tr} Q(\hat{\xi}_0(n) - \xi)(\hat{\xi}_0(n) - \xi)'] \\ &= E[\{\text{vec}(\hat{\xi}_0(n) - \xi)\}' (I \otimes Q) \text{vec}(\hat{\xi}_0(n) - \xi)] \\ &= \text{tr}(I \otimes Q) \text{Cov}(\text{vec } \hat{\xi}_0(n)) \\ &= \text{tr}(I \otimes Q) \{(A_n A_n')^{-1} \otimes (B' \Sigma^{-1} B)^{-1}\} \\ &= \text{tr}(A_n A_n')^{-1} \text{tr} Q (B' \Sigma^{-1} B)^{-1}, \end{aligned}$$

where the notation $\text{vec } \xi$ denotes $qr \times 1$ vector $(\xi_1', \dots, \xi_r')'$ for $\xi = (\xi_1, \dots, \xi_r)$ and $A \otimes B$ stands for kronecker product defined by $(a_{ij} B)$ for $A = (a_{ij})$. Hence we get that $R_1(\omega, \hat{\xi}_0(n^*)) \leq \varepsilon$, all ω for integer n^* defined by

$$n^* = \text{smallest integer } n (\geq m_0) \text{ such that}$$

$$(1.2) \quad [\text{tr}(A_n A_n')^{-1}]^{-1} \geq \text{tr} Q (B' \Sigma^{-1} B)^{-1} / \varepsilon.$$

Since Σ is unknown, however, there does not exist any fixed sample size such that Problem (1) holds. So, it is desired to obtain an estimation procedure resolving Problem (1). Recently Kubokawa (1988e) treated a similar problem with respect to the covariance criterion. For our purpose, arguments used there are heavily exploited.

In Section 2, based on the idea of Stein (1945), we construct a two-stage estimation rule for Problem (1), which is a multivariate extension of Rao (1973). Also the efficiency is discussed. A two-stage procedure proposed by Takada (1988b) in the ordinary multivariate case $[p=q, r=1, B=I, a_1=1]$ is consistent, but it is not asymptotically efficient. The procedure given in Section 2 just possesses both properties. Section 3 shows that the two-stage estimator in Section 2 is improved on by combined estimators when an additional sample is taken. Two-stage procedures resolving Problem (2) are developed in Section 4.

2. TWO-STAGE ESTIMATION PROCEDURES FOR ξ

2.1 A consistent two-stage procedure. For preassigned number $\varepsilon > 0$, we propose the following two-stage sampling rule.

(i) Start with m observations x_1, x_2, \dots, x_m for $m \geq \max(m_0, p-q+r+3)$, each x_i having $N_p(B\xi a_i, \Sigma)$.

(ii) Define the stopping number by

$N =$ smallest integer n ($\geq m$) such that

$$(2.1) \quad [\text{tr}(A_n A_n')^{-1}]^{-1} \geq k_m \text{tr} Q(B'S_m^{-1}B)^{-1}/\varepsilon,$$

where

$$(2.2) \quad k_m = (m-r-1)/\{(m-p+q-r-1)(m-p+q-r-2)\}$$

and $S_m = X_m(I - A_m'(A_m A_m')^{-1}A_m)X_m'$ with $X_m = (x_1, \dots, x_m)$, $A_m = (a_1, \dots, a_m)$.

(iii) Take a sample of size $N-m$, and estimate ξ by

$$(2.3) \quad \hat{\xi}_N = (B'S_m^{-1}B)^{-1}B'S_m^{-1}X_N A_N' (A_N A_N')^{-1},$$

for $X_N = (X_m, x_{m+1}, \dots, x_N)$ and $A_N = (A_m, a_{m+1}, \dots, a_N)$.

Then we get

Theorem 2.1. (consistency) The estimator $\hat{\xi}_N$ given by (2.3) is a solution of Problem (1).

Proof. Since $X_N A'_N = X_m A'_m + x_{m+1} a'_{m+1} + \dots + x_N a'_N$, the independence of $X_m A'_m$ and S_m gives that the conditional distribution of $X_N A'_N$ given S_m has $N_{p,r}(B \Sigma A'_N A_N; \Sigma, A_N A'_N)$. Thereby,

$$\begin{aligned} \text{Cov}(\text{vec } \hat{\xi}_N) &= E[\text{Cov}(\text{vec } \hat{\xi}_N | S_m)] \\ &= E[(A_N A'_N)^{-1} \otimes G(S_m, \Sigma)], \end{aligned}$$

where

$$G(S_m, \Sigma) = (B' S_m^{-1} B)^{-1} B' S_m^{-1} \Sigma S_m^{-1} B (B' S_m^{-1} B)^{-1}$$

and $\text{Cov}(\cdot | S_m)$ designates the conditional covariance matrix given S_m . Note that $G(S_m, \Sigma)$ is independent of $B' S_m^{-1} B$ by lemma 2.1 of Sugiura and Kubokawa (1988). Then $G(S_m, \Sigma)$ is independent of N , which implies that

$$\begin{aligned} \text{Cov}(\text{vec } \hat{\xi}_N) &= E[(A_N A'_N)^{-1}] \otimes E[G(S_m, \Sigma)] \\ &= \frac{m-r-1}{m-p+q-r-1} E[(A_N A'_N)^{-1}] \otimes (B' \Sigma^{-1} B)^{-1}, \end{aligned}$$

since $E[G(S_m, \Sigma)] = \{(m-r-1)/(m-p+q-r-1)\} (B' \Sigma^{-1} B)^{-1}$ as shown by Rao (1967), Williams (1967), Gleser and Olkin (1972) and Sugiura and Kubokawa (1988). Hence from (1.1) and the definition of N given by (2.1), we obtain that

$$\begin{aligned} (2.4) \quad R_1(\omega, \hat{\xi}_N) &= \text{tr}(I \otimes Q) \text{Cov}(\text{vec } \hat{\xi}_N) \\ &= \frac{m-r-1}{m-p+q-r-1} E[\text{tr}(A_N A'_N)^{-1}] \text{tr} Q (B' \Sigma^{-1} B)^{-1} \\ &\leq \varepsilon (m-p+q-r-2) E[\text{tr} Q (B' \Sigma^{-1} B)^{-1} / \text{tr} Q (B' S_m^{-1} B)^{-1}]. \end{aligned}$$

Here, $\text{tr} Q (B' S_m^{-1} B)^{-1} = \text{tr} W (B' \Sigma^{-1} B)^{-1/2} Q (B' \Sigma^{-1} B)^{-1/2}$ for $W = (B' \Sigma^{-1} B)^{1/2} (B' S_m^{-1} B)^{-1} (B' \Sigma^{-1} B)^{1/2}$ having $W_q(m-p+q-r, I)$. Denote $\text{diag}(\sigma_1, \dots, \sigma_q) = H' (B' \Sigma^{-1} B)^{-1/2} Q (B' \Sigma^{-1} B)^{-1/2} H$ for some orthogonal matrix H .

From the Bartlett's decomposition, we have

$$(2.5) \quad \text{tr} Q (B' S_m^{-1} B)^{-1} = \sum_{i=1}^q \sigma_i W_i,$$

where W_1, \dots, W_q are mutually independent random variables, each

being distributed as $\chi^2_{m-p+q-r}$. Letting

$$(2.6) \quad \lambda_i = \sigma_i / \sum_{j=1}^q \sigma_j, \quad i=1, \dots, q,$$

we can see that

$$(2.7) \quad E[\text{tr}Q(B'\Sigma^{-1}B)^{-1} / \text{tr}Q(B'S_m^{-1}B)^{-1}] = E[(\sum_{i=1}^q \lambda_i W_i)^{-1}],$$

$$(2.8) \quad E[W_i^{-1}] = (m-p+q-r-2)^{-1}, \quad i=1, \dots, q.$$

Therefore from (2.4), (2.7) and (2.8), we can get the required conclusion if the following inequality holds:

$$(2.9) \quad E[(\sum_{i=1}^q \lambda_i W_i)^{-1}] \leq \max_{1 \leq i \leq q} \{E[W_i^{-1}]\}.$$

The case of $q=2$ follows from the convexity of $f(\lambda_1) = E[\{\lambda_1 W_1 + (1-\lambda_1)W_2\}^{-1}]$. When $q \geq 3$, by induction, we have

$$\begin{aligned} E[(\sum_{i=1}^q \lambda_i W_i)^{-1}] &= E[\{\lambda_q W_q + (1-\lambda_q)(\sum_{i=1}^{q-1} \lambda_i W_i / \sum_{j=1}^{q-1} \lambda_j)\}^{-1}] \\ &\leq \max\{E[W_q^{-1}], E[(\sum_{i=1}^{q-1} (\lambda_i / \sum_{j=1}^{q-1} \lambda_j) W_i)^{-1}]\} \\ &\leq \max_{1 \leq i \leq q} \{E[W_i^{-1}]\}, \end{aligned}$$

which establishes (2.9), and the proof of Theorem 2.1 is complete.

Now we show the asymptotic efficiency of the stopping number in the sense of Chow and Robbins (1965), that is, $\lim_{\varepsilon \rightarrow 0} E[N]/n^* = 1$. The method is due to that of Mukhopadhyay (1980) for the univariate case.

Theorem 2.2. (asymptotic efficiency) Assume that $n^{-1}(A_n A_n') \rightarrow Q > 0$ as $n \rightarrow \infty$, and that $m = O(\varepsilon^{-d})$ for $0 < d < 1$. Then $\lim_{\varepsilon \rightarrow 0} E[N]/n^* = 1$.

Proof. For simplicity, denote $g(n) = n \text{tr}(A_n A_n')^{-1}$, which converges to $\text{tr} \Omega^{-1}$ as n tends to infinity. From the definitions of n^* and N given by (1.2) and (2.1) respectively,

$$\begin{aligned} k_m g(N) \text{tr} Q(B' S_m^{-1} B)^{-1} \left[\frac{n^*}{n^* - 1} g(n^* - 1) \text{tr} Q(B' \Sigma^{-1} B)^{-1} + m_0 \varepsilon \right]^{-1} &< N/n^* \\ &< [k_m \cdot \frac{N}{N-1} g(N-1) \text{tr} Q(B' S_m^{-1} B)^{-1} + \varepsilon m] [g(n^*) \text{tr} Q(B' \Sigma^{-1} B)^{-1}]^{-1}. \end{aligned}$$

Note that if ε tends to zero, then $m \rightarrow \infty$, $\varepsilon m \rightarrow 0$, $n^* \rightarrow \infty$, $N \rightarrow \infty$ a.s., $\text{tr} Q(B' S_m^{-1} B)^{-1} / (m-p+q-r) \rightarrow \text{tr} Q(B' \Sigma^{-1} B)^{-1}$ a.s.. Hence we can get the required conclusion if the followings hold:

$$(2.10) \quad \lim_{\varepsilon \rightarrow 0} E[g(N) \text{tr} Q(B' S_m^{-1} B)^{-1} / (m-p+q-r)] = \text{tr} \Omega^{-1} \text{tr} Q(B' \Sigma^{-1} B)^{-1},$$

$$(2.11) \quad \lim_{\varepsilon \rightarrow 0} E\left[\frac{N}{N-1} g(N-1) \text{tr} Q(B' S_m^{-1} B)^{-1} / (m-p+q-r)\right] = \text{tr} \Omega^{-1} \text{tr} Q(B' \Sigma^{-1} B)^{-1}.$$

For (2.10), it must be shown that $g(N) \text{tr} Q(B' S_m^{-1} B)^{-1} / (m-p+q-r)$ is bounded above by an integrable function which is independent of ε . Since $\lim_{\varepsilon \rightarrow 0} g(n) = \text{tr} \Omega^{-1}$, there is some n_0 such that for any $n > n_0$, $g(n) < \text{tr} \Omega^{-1} + 1$. Hence for $N > n_0$, $g(N) < \text{tr} \Omega^{-1} + 1$, so that for any $N \geq 1$,

$$g(N) < g(1) + \dots + g(n_0) + \{\text{tr} \Omega^{-1} + 1\} = c_0 \quad (\text{say}).$$

Then from (2.5),

$$\begin{aligned} g(N) \text{tr} Q(B' S_m^{-1} B)^{-1} / (m-p+q-r) &\leq c_0 \sum_{i=1}^q \sigma_i W_i / (m-p+q-r) \\ &\leq q c_0 \max_{1 \leq i \leq q} (\sigma_i) \sup_{m \geq m_0} \{T_m\}, \end{aligned}$$

where $T_m = \sum_{i=1}^q W_i / \{q(m-p+q-r)\}$. Since $\sum_{i=1}^q W_i \sim \chi_{q(m-p+q-r)}^2$, lemma 3 of Simons (1968) implies that T_m is a reversed martingale, so that by Doob's inequality,

$$E[\sup_{m \geq m_0} (T_m)] \leq \frac{e}{e-1} \{1 + E[T_{m_0} \log^+ T_{m_0}]\} < \infty,$$

where $\log^+ u = \max(\log u, 1)$. This inequality means that

$g(N) \text{tr} Q(B' S_m^{-1} B)^{-1} / (m-p+q-r)$ is bounded above by the integrable

function independent of ε . Finally, applying the dominated convergence theorem, we get (2.10). Similarly, we can verify (2.11) and Theorem 2.2 is proved.

Remark. In the ordinary multivariate case [$p=q, r=1, B=I, a_1=1$], Takada (1988b) proposed the stopping number

$$N = \max\left\{\left[\frac{p}{\varepsilon(m-p-2)} \text{ch}_{\max}(S_m)\right] + 1, m\right\},$$

where $[u]$ designates the integer part of u and $\text{ch}_{\max}(S_m)$ is the largest characteristic root of S_m . As remarked in the paper, his two-stage procedure is consistent but is not asymptotically efficient when $p \geq 2$. For any p , our procedure satisfies the requirements of both consistency and asymptotic efficiency.

As a measure of stronger efficiency, Simons (1968) and Star and Woodroffe (1968) considered an asymptotically bounded regret, that is, $\lim_{\varepsilon \rightarrow 0} E[N - n^*] < \infty$, and Ghosh and Mukhopadhyay (1981) called it second order efficiency. Takada (1988a) demonstrated that Rao's two-stage method is not second order asymptotically efficient. It is shown that the same result holds in our general model.

Theorem 2.3. Assume that $\text{ntr}(A_n A_n')^{-1} = \text{tr} \Omega^{-1} + o(n^{-1})$, and that $m = O(\varepsilon^{-d})$, $\lim_{\varepsilon \rightarrow 0} \varepsilon^d m > 0$ for $1/2 \leq d < 1$. Then $\lim_{\varepsilon \rightarrow 0} E[N - n^*] = \infty$.

Proof. From the definitions of n^* and N ,

$$\begin{aligned} E[N - n^*] &\geq \frac{1}{\varepsilon} \{k_m E[g(N) \text{tr} Q(B' S_m^{-1} B)^{-1}] - \frac{n^*}{n^* - 1} g(n^* - 1) \text{tr} Q(B' \Sigma^{-1} B)^{-1}\} - m_0 \\ (2.12) \quad &= \frac{1}{\varepsilon} \{k_m E[\text{tr} Q(B' S_m^{-1} B)^{-1}] - \frac{n^*}{n^* - 1} \text{tr} Q(B' \Sigma^{-1} B)^{-1}\} \text{tr} \Omega^{-1} - m_0 \\ &\quad + \frac{1}{\varepsilon} k_m E[D_N \text{tr} Q(B' S_m^{-1} B)^{-1}] - \frac{n^*}{n^* - 1} \cdot \frac{1}{\varepsilon} D_{n^* - 1} \text{tr} Q(B' \Sigma^{-1} B)^{-1}, \end{aligned}$$

where $D_n = g(n) - \text{tr} \Omega^{-1}$. Also the definition of N gives that

$$\frac{1}{\varepsilon} k_m \text{tr} Q(B' S_m^{-1} B)^{-1} > [\text{tr}(A_{N-1}' A_{N-1})^{-1}]^{-1} = \frac{N-1}{g(N-1)},$$

so that

$$(2.13) \quad \frac{1}{\varepsilon} k_m E[D_N \text{tr} Q(B' S_m^{-1} B)^{-1}] > E\left[\frac{1}{g(N-1)} \cdot \frac{N-1}{N} N D_N\right].$$

Since $g(n-1) \rightarrow \text{tr} \Omega^{-1}$ and $n D_n = O(1)$ as $n \rightarrow \infty$, it can be seen that the r.h.s. in (2.13) is bounded below. Clearly, $n^* \{\varepsilon(n^*-1)\}^{-1} D_{n^*-1} \text{tr} Q(B' \Sigma^{-1} B)^{-1}$ is bounded above, so that for some constant M_0 ,

$$(2.14) \quad \begin{aligned} E[N - n^*] &\geq \frac{1}{\varepsilon} \{k_m(m-p+q-r)-1\} \text{tr} \Omega^{-1} \text{tr} Q(B' \Sigma^{-1} B)^{-1} + M_0 \\ &= \frac{p-q+2}{\varepsilon m} \cdot \frac{m^2}{(m-p+q-r-1)(m-p+q-r-2)} \text{tr} \Omega^{-1} \text{tr} Q(B' \Sigma^{-1} B)^{-1} \\ &\quad + (\varepsilon m^2)^{-1} O(1) + M_0. \end{aligned}$$

Noting that $\lim_{\varepsilon \rightarrow 0} \varepsilon m = 0$ and $\lim_{\varepsilon \rightarrow 0} \varepsilon m^2 > 0$ by the assumptions, we can see that the r.h.s. in the equality of (2.14) approaches infinity as ε tends to zero, which establishes Theorem 2.3.

2.2. An asymptotically consistent procedure. Instead of Problem 1, Takada (1988a) considered the relaxed problem requiring asymptotic consistency and found a procedure with both asymptotic consistency and an asymptotically bounded risk in the univariate nonparametric model.

Problem (1'). (asymptotic consistency) We want to estimator $d = d(\varepsilon)$ of ξ such that

$$\lim_{\varepsilon \rightarrow 0} R_1(\omega, d)/\varepsilon \leq 1.$$

Of course, the two-stage procedure in Section 2.1 is asymptotically consistent. To obtain a procedure with an asymptotically bounded risk, we modify the stopping number given by (2.1) as follows:

N = smallest integer n ($\geq m$) such that

$$(2.15) \quad [\text{tr}(A_n A_n')^{-1}]^{-1} \geq (m-p+q)^{-1} \text{tr} Q(B' S_m^{-1} B)^{-1} / \varepsilon.$$

Then from the proof of Theorem 2.1 we can see that $R_1(\omega, \hat{\xi}_N) / \varepsilon \leq (m-r-1)(m-p+q-r) / \{(m-p+q-r-1)(m-p+q-r-2)\}$, which implies that $\lim_{\varepsilon \rightarrow 0} \{R_1(\omega, \hat{\xi}_N) / \varepsilon\} \leq 1$ if $m \rightarrow \infty$ as $\varepsilon \rightarrow 0$.

Theorem 2.4. (asymptotic consistency) Assume that $m = O(\varepsilon^{-d})$, $0 < d < 1$, and that the stopping number N is given by (2.15). Then the estimator $\hat{\xi}_N$ is asymptotically consistent.

By the same arguments as used in the proofs of Theorems 2.2 and 2.3, we can show the following theorems.

Theorem 2.5. (asymptotic efficiency) Under the conditions of Theorem 2.2, $\lim_{\varepsilon \rightarrow 0} E[N] / n^* = 1$.

Theorem 2.6. Under the conditions of Theorem 2.3, $\lim_{\varepsilon \rightarrow 0} E[N - n^*] < \infty$.

3. IMPROVING ON THE TWO-STAGE ESTIMATION PROCEDURES WHEN AN ADDITIONAL SAMPLE IS AVAILABLE

In this section, we discuss two-sample problem. Assume that for the principal estimation of ξ , sample x_1, \dots, x_N is obtained based on the two-stage sampling rule in Section 2, each x_i having $N_p(B\xi a_i, \Sigma)$. We further assume that supplementary observations Y ($p \times q$) are taken where Y has $N_{p,q}(D\xi C; \Psi, I_q)$ with known matrices D ($p \times q$, rank q), C ($r \times q$, rank r), unknown positive definite matrix Ψ and the common coefficient matrix ξ . Using information of the

additional sample, we want to construct an estimator superior to $\hat{\xi}_N$ defined by (2.3).

This problem of estimating the common parameters has been studied by Graybill and Deal (1959), Brown and Cohen (1974), Khatri and Shah (1974), Bhattacharya (1980), Sugiura and Kubokawa (1988) and Kubokawa (1987a,b,c;1988a,b). Recently Kubokawa (1988c) presented an improved combined procedure in the above situation with $p=q=r=1$. This multivariate extension is given here. Since MLE based on only Y is

$$\hat{\xi}_Y = (D'TD)^{-1}D'T^{-1}YC'(CC')^{-1} \quad \text{for } T=Y(I-C'(CC')^{-1}C)Y',$$

we consider a combined estimator of $\hat{\xi}_N$ and $\hat{\xi}_Y$ of the form

$$(3.1) \quad \tilde{\xi}_N(a, b_N) = \hat{\xi}_N + a(1+R_N)^{-1}(\hat{\xi}_Y - \hat{\xi}_N),$$

where

$$R_N = \frac{(m-p+q-r-1)(\lambda-r-1)\text{tr}(CC')^{-1}\text{tr}Q(D'T^{-1}D)^{-1}}{(m-r-1)(\lambda-p+q-r-1)\text{tr}(A_N A_N')^{-1}\text{tr}Q(B'S_m^{-1}B)^{-1}} b_N,$$

where a and b_N are positive constants.

Theorem 3.1. Assume that

- (a) $\text{tr}(A_N A_N')^{-1} b_N$ is decreasing with $\lim_{n \rightarrow \infty} \text{tr}(A_N A_N')^{-1} b_N = 0$,
- (b) b_N is nondecreasing,
- (c) $a \leq 2(\lambda-p+q-r-4)b_m / (m-p+q-r+2)$ for $\lambda > p-q+r+4$.

Then $R_1(\omega, \tilde{\xi}_N(a, b_N)) \leq R_1(\omega, \hat{\xi}_N)$ for all ω .

Proof. Without the loss of generality, suppose that the stopping number N is given by (2.1). For $\phi_N = a(1+R_N)^{-1}$, the risk difference is represented as

$$\begin{aligned} & R(\omega, \tilde{\xi}_N(a, b_N)) - R(\omega, \hat{\xi}_N) \\ &= E[\phi_N^2 \{ \text{tr}Q(\hat{\xi}_Y - \xi)(\hat{\xi}_Y - \xi)' + \text{tr}Q(\hat{\xi}_N - \xi)(\hat{\xi}_N - \xi)' \} - 2\phi_N \text{tr}Q(\hat{\xi}_N - \xi)(\hat{\xi}_N - \xi)'] \end{aligned}$$

$$\begin{aligned}
&= E[\phi_N^2 \{ \frac{\ell-r-1}{\ell-p+q-r-1} \text{tr}(CC')^{-1} \text{tr}Q(D'\Psi^{-1}D)^{-1} \\
(3.2) \quad &+ \frac{m-r-1}{m-p+q-r-1} \text{tr}(A_N A_N')^{-1} \text{tr}Q(B'\Sigma^{-1}B)^{-1} \} \\
&\quad - 2\phi_N \cdot \frac{m-r-1}{m-p+q-r-1} \text{tr}(A_N A_N')^{-1} \text{tr}Q(B'\Sigma^{-1}B)^{-1}] \\
&= a \frac{m-r-1}{m-p+q-r-1} \text{tr}Q(B'\Sigma^{-1}B)^{-1} E[\text{tr}(A_N A_N')^{-1} \{ \frac{(1+\theta_N)a}{(1+\theta_N Q_N)^2} - \frac{2}{1+\theta_N Q_N} \}],
\end{aligned}$$

where

$$\theta_N = \frac{(m-p+q-r-1)(\ell-r-1) \text{tr}(CC')^{-1} \text{tr}Q(D'\Psi^{-1}D)^{-1}}{(m-r-1)(\ell-p+q-r-1) \text{tr}(A_N A_N')^{-1} \text{tr}Q(B'\Sigma^{-1}B)^{-1}},$$

and $Q_N = R_N / \theta_N$. Here by the inequality (2.5) of Kubokawa (1988c),

$$(1+\theta_N)a(1+\theta_N Q_N)^{-2} - 2(1+\theta_N Q_N)^{-1} \leq a(1+\theta_N a)^{-1}(aQ_N^{-2} - 2Q_N^{-1}),$$

which yields that $R_1(\omega, \tilde{\xi}_N(a, b_N)) \leq R_1(\omega, \hat{\xi}_N)$ for all ω if

$$\begin{aligned}
(3.3) \quad E[\frac{\text{tr}(A_N A_N')^{-1}}{1+\theta_N a} \{ a(\frac{\text{tr}Q(D'\Psi^{-1}D)^{-1}}{\text{tr}Q(D'T^{-1}D)^{-1}} \cdot \frac{\text{tr}Q(B'S_m^{-1}B)^{-1}}{\text{tr}Q(B'\Sigma^{-1}B)^{-1}} b_N^{-1})^2 \\
- 2 \frac{\text{tr}Q(D'\Psi^{-1}D)^{-1}}{\text{tr}Q(D'T^{-1}D)^{-1}} \cdot \frac{\text{tr}Q(B'S_m^{-1}B)^{-1}}{\text{tr}Q(B'\Sigma^{-1}B)^{-1}} b_N^{-1} \}] \leq 0
\end{aligned}$$

for all ω . Similar to (2.7),

$$\begin{aligned}
\frac{E[\text{tr}Q(D'\Psi^{-1}D)^{-1} / \text{tr}Q(D'T^{-1}D)^{-1}]}{E[\{ \text{tr}Q(D'\Psi^{-1}D)^{-1} / \text{tr}Q(D'T^{-1}D)^{-1} \}^2]} &= \frac{E[(\sum_{i=1}^q \eta_i V_i)^{-1}]}{E[(\sum_{i=1}^q \eta_i V_i)^{-2}]} \\
(3.4) \quad &\geq \min_{1 \leq i \leq q} \{ \frac{E[V_i^{-1}]}{E[V_i^{-2}]} \},
\end{aligned}$$

where V_1, \dots, V_q are mutually independent random variables, each V_i

$\sim \chi_{\ell-p+q-r}^2$ and η_1, \dots, η_q are parameters satisfying $\sum_{i=1}^q \eta_i = 1$ and $\eta_i > 0$, $i=1, \dots, q$. Here the inequality in (3.4) follows from

theorem 2.2 of Bhattacharya (1984). Since $E[V_i^{-1}] / E[V_i^{-2}] = \ell-p+q-r-$

4, the inequality (3.3) holds if $E[\alpha_N U_m (U_m - \beta_N \sigma)] \leq 0$ for all ω ,

which is rewritten as

$$(3.5) \quad h(\omega) \stackrel{\text{def}}{=} \sum_{n=m}^{\infty} \alpha_n E[U_m(U_m - \beta_n \sigma) I_{[N=n]}] \leq 0 \quad \text{for all } \omega,$$

where $U_m = \text{tr} Q(B' S_m^{-1} B)^{-1}$, $\sigma = \text{tr} Q(B' \Sigma^{-1} B)^{-1}$, $\alpha_N = \text{tr}(A_N A_N')^{-1} (1 + \theta_N a)^{-1} b_N^{-2}$, $\beta_N = (2/a)(\lambda - p + q - r - 4) b_N$, and $I_{[N=n]} = 1$ if $[\text{tr}(A_{n-1} A_{n-1}')^{-1}]^{-1} < k_m U_m / \varepsilon \leq [\text{tr}(A_n A_n')^{-1}]^{-1}$; $= 0$ otherwise.

To prove (3.5), the arguments used in Ghosh, Nickerson and Sen (1987) are available. Let n_0 denote the smallest integer ($\geq m$) such that $\varepsilon / \{k_m \text{tr}(A_n A_n')^{-1}\} \geq \beta_n \sigma$. By the condition (a), the n_0 is uniquely determined. Then we write

$$(3.6) \quad h(\omega) = \sum_{n=m}^{n_0-1} \alpha_n E[U_m(U_m - \beta_n \sigma) I_{[N=n]}] + \alpha_{n_0} E[U_m(U_m - \beta_{n_0} \sigma) I_{[N \geq n_0]}] \\ + \sum_{n=n_0}^{\infty} \{ \alpha_{n+1} E[U_m(U_m - \beta_{n+1} \sigma) I_{[N \geq n+1]}] - \alpha_n E[U_m(U_m - \beta_n \sigma) I_{[N \geq n+1]}] \},$$

where the first term in the r.h.s. of (3.6) should be interpreted as zero if $n_0 = m$. From the definition of N , on the set $\{N \geq n+1\}$,

$U_m > \varepsilon [k_m \text{tr}(A_n A_n')^{-1}]^{-1} \geq \beta_n \sigma$ when $n \geq n_0$. Since α_n and β_n are nonincreasing and nondecreasing in n , respectively, by the condition (b), we get

third term in the r.h.s. of (3.6)

$$(3.7) \quad \leq \sum_{n=n_0}^{\infty} \alpha_{n+1} \{ E[U_m(U_m - \beta_{n+1} \sigma) I_{[N \geq n+1]}] - E[U_m(U_m - \beta_n \sigma) I_{[N \geq n+1]}] \} \\ = \sum_{n=n_0}^{\infty} \alpha_{n+1} (\beta_n - \beta_{n+1}) \sigma E[U_m I_{[N \geq n+1]}] \\ \leq 0.$$

Next, on the set $\{N=n\}$, $U_m < \beta_n \sigma$ when $n \leq n_0 - 1$. Thus from the monotonicity of β_n ,

first two terms in the r.h.s. of (3.6)

$$\leq \alpha_{n_0} \sum_{n=m}^{n_0-1} E[U_m(U_m - \beta_n \sigma) I_{[N=n]}] + \alpha_{n_0} E[U_m(U_m - \beta_{n_0} \sigma) I_{[N \geq n_0]}] \\ \leq \alpha_{n_0} \sum_{n=m}^{n_0-1} E[U_m(U_m - \beta_m \sigma) I_{[N=n]}] + \alpha_{n_0} E[U_m(U_m - \beta_m \sigma) I_{[N \geq n_0]}]$$

$$\begin{aligned}
 (3.8) \quad &= \alpha_{n_0} E[U_m(U_m - \beta_m \sigma)] \\
 &= \alpha_{n_0} \sigma E[U_m] \{E[U_m^2/\sigma^2]/E[U_m/\sigma] - \beta_m\}.
 \end{aligned}$$

Finally from (2.7),

$$\begin{aligned}
 E[U_m^2/\sigma^2]/E[U_m/\sigma] &= E[(\sum_{i=1}^q \lambda_i W_i)^2]/E[\sum_{i=1}^q \lambda_i W_i] \\
 (3.9) \quad &\leq \max_{1 \leq i \leq q} \{E[W_i^2]/E[W_i]\}.
 \end{aligned}$$

The inequality in (3.9) can be verified by the same arguments as in the proof of theorem 2.2 of Bhattacharya (1984). Since $E[W_i^2]/E[W_i] = m - p + q - r + 2$, it can be seen that the r.h.s. in the last equality of (3.8) is not positive by the condition (c). Hence, together with (3.6) and (3.7), the required inequality (3.5) is established and the proof of Theorem 3.1 is complete.

4. TWO-STAGE ESTIMATION PROCEDURES FOR POWERS OF THE GENERALIZED VARIANCE $|\Sigma|^\alpha$

4.1. A consistent two-stage procedure. Now we look for a solution of Problem 2. Define the statistic $f_n(x_1, \dots, x_n)$ based on data (x_1, \dots, x_n) by

$$f_n(x_1, \dots, x_n) = X_n (I - A_n' (A_n A_n')^{-1} A_n) X_n'$$

for $X_n = (x_1, \dots, x_n)$ and $A_n = (a_1, \dots, a_n)$, and denote

$$g_n = 1 - \{\Gamma_p(\frac{n-r}{2} + \alpha)\}^2 / \{\Gamma_p(\frac{n-r}{2} + 2\alpha) \Gamma_p(\frac{n-r}{2})\},$$

where $\Gamma_p(x) = \pi^{p(p-1)/4} \prod_{i=1}^p \Gamma(x - (i-1)/2)$. Then we consider the following two-stage sampling rule.

(i) Start with m observations x_1, \dots, x_m for $m \geq \max(m_0, r+1, r+4\alpha)$.

(ii) Define the stopping number by

$N =$ smallest integer $n \geq n_1 = \max(m_0, r+1, r-4\alpha)$ such that

$$(4.1) \quad g_n^{-1} \geq h_m |S_m|^{2\alpha},$$

where $S_m = f_m(x_1, \dots, x_m)$ and $h_m = \Gamma_p(\frac{m-r}{2} - 2\alpha) / \{\varepsilon 2^{2\alpha p} \Gamma_p(\frac{m-r}{2})\}$.

(iii) Take a sample x_{m+1}, \dots, x_{m+N} , and estimate $|\Sigma|^\alpha$ by

$$(4.2) \quad \delta_N = c_N |T_N|^\alpha,$$

where $T_N = f_N(x_{m+1}, \dots, x_{m+N})$ and

$$(4.3) \quad c_N = \Gamma_p(\frac{N-r}{2} + \alpha) / \{2^{\alpha p} \Gamma_p(\frac{N-r}{2} + 2\alpha)\}.$$

Theorem 4.1. (consistency) The estimator δ_N given by (4.2) is a solution of Problem 2, that is, $R_2(\omega, \delta_N) \leq \varepsilon$ for all ω .

Proof. We first note that the conditional distribution of T_N given S_m has $W_p(N-r, \Sigma)$. From the definition (4.1) and the fact that $E[|T_N|^\alpha | S_m] = |\Sigma|^\alpha 2^{\alpha p} \Gamma_p((N-r)/2 + \alpha) / \Gamma_p((N-r)/2)$, it follows that

$$R_2(\omega, \delta_N) = E[g_N] |\Sigma|^{2\alpha} \leq h_m^{-1} E[|S_m|^{-2\alpha}] |\Sigma|^{2\alpha} = \varepsilon,$$

getting the desired result.

4.2. Improving on the two-stage procedure by using information in the first stage sample. By Theorem 4.1, the estimator δ_N is certainly a solution of Problem 2. However, the estimator seems to be unsatisfactory because only the data of the second stage are used for estimation of $|\Sigma|^\alpha$. So we ask the question whether it is possible to improve on the estimator by using the information gathered in the first stage. For this question, based on Kubokawa (1988d), we consider the combined estimator

$$(4.4) \quad \delta_N^*(d_N) = \delta_N + d_N |S_m|^\alpha,$$

where d_n is a suitable constant depending on n .

Theorem 4.2. Assume that

(a) $(d_n/g_n)^2/g_n$ is increasing in n with $\lim_{n \rightarrow \infty} (d_n/g_n)^2/g_n = \infty$,

(b) d_n and d_n/g_n are nonincreasing in n ,

(c) $d_{n_1}/g_{n_1} \leq 2c_m$ where c_m is given by (4.3) with $N=m$.

Then $R_2(\omega, \delta_N^*(d_N)) \leq R_2(\omega, \delta_N)$ for all ω .

Proof. The risk function of $\delta_N^*(d_N)$ is written by

$$R_2(\omega, \delta_N^*(d_N)) = R_2(\omega, \delta_N) + E[d_N^2 |S_m|^{2\alpha} - 2d_N |S_m|^\alpha E[(|\Sigma|^\alpha - \delta_N) | S_m]]$$

and we observe that $E[(|\Sigma|^\alpha - \delta_N) | S_m] = g_N$, so that it suffices to show that for all ω ,

$$E[d_N^2 |S_m|^\alpha \{ |S_m|^\alpha - (2g_N/d_N) |\Sigma|^\alpha \}] \leq 0,$$

which can be proved by the same arguments as in the proof of Theorem 3.1 under the conditions (a), (b) and (c) of Theorem 4.2.

Letting $d_n = ag_n$ for positive constant a , we get a corollary by the following lemma.

Lemma 4.3. g_n is decreasing in n with $\lim_{n \rightarrow \infty} g_n = 0$.

Proof. From the definition of $\Gamma_p(\cdot)$,

$$\frac{\{\Gamma_p(n/2+\alpha)\}^2}{\Gamma_p(n/2+2\alpha)\Gamma_p(n/2)} = \prod_{i=1}^p \frac{\{\Gamma([n-i+1]/2+\alpha)\}^2}{\Gamma((n-i+1)/2+2\alpha)\Gamma((n-i+1)/2)},$$

so that it suffices to show that $\{\Gamma(t+\alpha)\}^2/\{\Gamma(t+2\alpha)\Gamma(t)\}$ is increasing in t . Since $\Gamma(t) = (te^{\gamma t})^{-1} \prod_{j=1}^{\infty} (1+t/j)^{-1} e^{t/j}$ by the Euler's infinite product [see Abramowitz and Stegun (1964, p.76)],

$$(4.5) \quad \frac{\{\Gamma(t+\alpha)\}^2}{\Gamma(t+2\alpha)\Gamma(t)} = \prod_{j=1}^{\infty} \frac{(t+2\alpha)t \cdot (j+t+2\alpha)(j+t)}{(t+\alpha)^2 (j+t+\alpha)^2}.$$

Clearly, the each component in the r.h.s. of (4.5) is increasing in t . Also we can observe that

$$\lim_{t \rightarrow \infty} \{\Gamma(t+\alpha)\}^2/\{\Gamma(t+2\alpha)\Gamma(t)\} = 1,$$

establishing Lemma 4.3.

Corollary 4.4. The estimator $\delta_N^*(a_{g_N}) = \delta_N + a_{g_N} |S_m|^\alpha$ is better than δ_N if $a \leq 2c_m$.

4.3. Further domination by Stein's method. On the basis of the result of Stein (1964), inadmissibility of the best affine equivariant estimator for $|E|^\alpha$ has been indicated by Shorrocks and Zidek (1976), Sinha (1976), Sinha and Ghosh (1987), Sugiura (1988a, 1988b) and Sugiura and Konno (1987, 1988). The purpose of this section is to show that the estimator $\delta_N^*(d_N)$ given by (4.4) is further dominated by Stein's method when $\alpha > 0$.

Denote $Z_N = (x_{m+1}, \dots, x_{m+N}) G_N' (G_N G_N')^{-1/2}$ and $\eta_N = B \xi (G_N G_N')^{-1/2}$ for $G_N = (a_{m+1}, \dots, a_{m+N})$. The Stein type estimator we look at is of the form

$$\delta_N^{**} = \min\left\{\delta_N, \frac{\Gamma_p(N/2+\alpha)}{\Gamma_p(N/2+2\alpha)} 2^{-\alpha p} |T_N + Z_N Z_N'|^\alpha\right\} + d_N |S_m|^\alpha, \quad \alpha > 0.$$

Note that Z_N and T_N are conditionally independent given S_m , and that given S_m , Z_N has $N_{p,r}(\eta_N; \Sigma, I_r)$. Then we get

Theorem 4.5. The estimator $\delta_N^*(d_N)$ is further dominated by δ_N^{**} when $\alpha > 0$.

Proof. Letting

$$\delta_S = \min\left\{\delta_N, \frac{\Gamma_p(N/2+\alpha)}{\Gamma_p(N/2+2\alpha)} 2^{-\alpha p} |T_N + Z_N Z_N'|^\alpha\right\},$$

we have

$$\begin{aligned} R_2(\omega, \delta_N^{**}) - R_2(\omega, \delta_N^*(d_N)) \\ &= R_2(\omega, \delta_S) - R_2(\omega, \delta_N) + 2E[(\delta_S - \delta_N) d_N |S_m|^\alpha] \\ &\leq R_2(\omega, \delta_S) - R_2(\omega, \delta_N) \end{aligned}$$

$$= E[E[(\delta_S - |\Sigma|^\alpha)^2 | S_m] - E[(\delta_N - |\Sigma|^\alpha)^2 | S_m]].$$

Here from the result of Sugiura (1988a),

$$E[(\delta_S - |\Sigma|^\alpha)^2 | S_m] - E[(\delta_N - |\Sigma|^\alpha)^2 | S_m] \quad \text{for all } \omega,$$

which proves Theorem 4.5.

Remark. It is interesting if we could find an estimator dominating $\delta_N^*(d_N)$ for $\alpha < 0$.
